# Agents

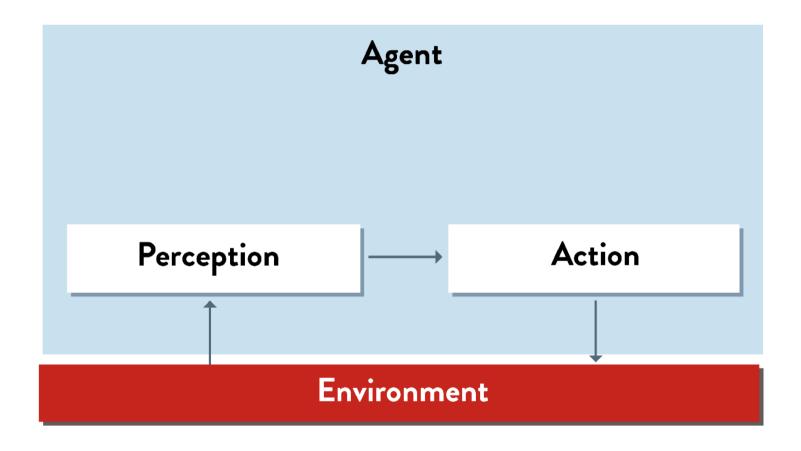

COMP3411/9814: Artificial Intelligence

# Types of Agents

- Reactive Agent
- Model-Based Agent
- Planning Agent
- Utility-based agent
- Game Playing Agent
- Learning Agent

# Agent Model

- Choose the next action based only on what agent currently perceives
  - Uses a "policy" or set of rules that are simple to apply
- Sometimes called "simple reflex agents"
  - but they can do surprisingly sophisticated things

#### repeat

Reflex (reactive) agent — applies condition-action rules to each percept

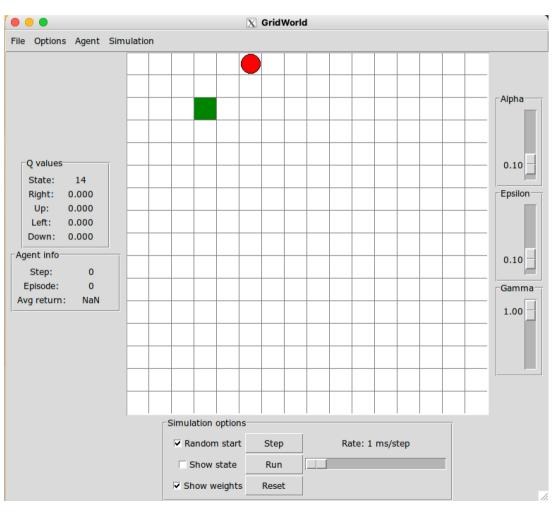

# **Reactive Robots**

# Limitations of Reactive Agents

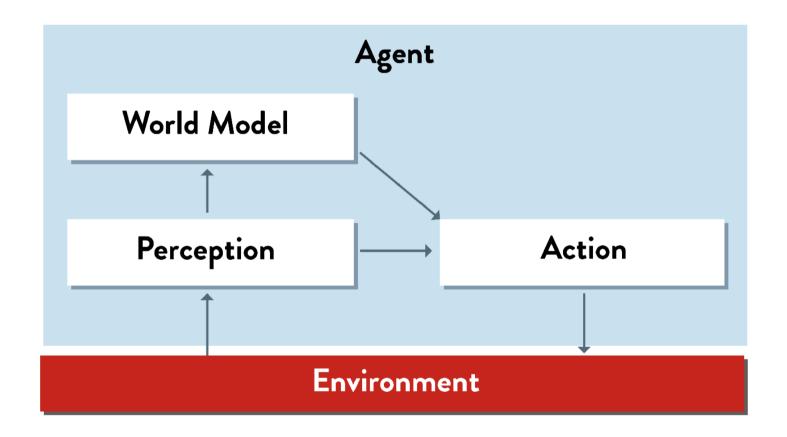

# Simulation of Reactive, Search and Learning Agents

### Limitations of Reactive Agents

- Reactive Agents have no memory or "state"
  - unable to base decision on previous observations
  - may repeat the same sequence of actions over and over
  - Escape from infinite loops is (sometimes) possible if the agent can randomise its actions.

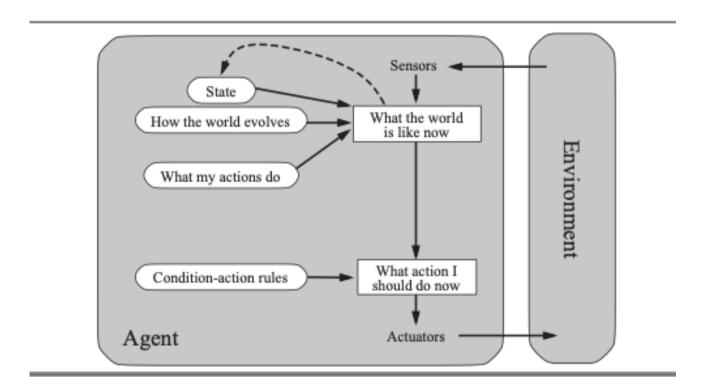

# Model-Based Agent

# Model-based Agents

- Handle partial observability by keeping track of the part of the world it can't see now.
- Maintain internal state that depends on the percept history and remembers at least some of the unobserved aspects of the current state.
- Knowledge about "how the world works" is called a model of the world.
- An agent that uses such a model is called a model-based agent.

#### Model-based Reflex Agent

A model-based reflex agent. It keeps track of the current state of the world, using an internal model. It then chooses an action in the same way as the reflex agent.

# Model-based Reflex Agent

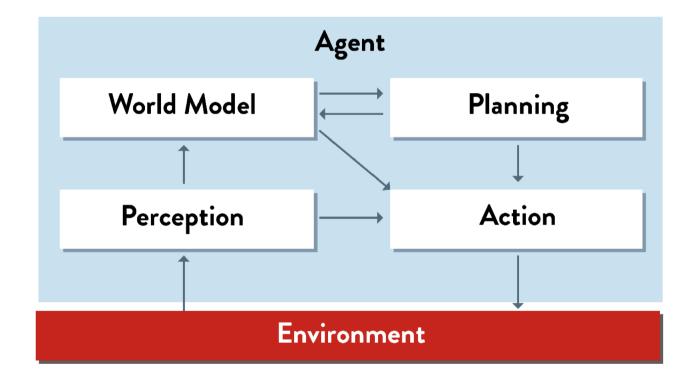

# Limitations of Model-Based Agents

- An agent with a world model but no planning can look into the past, but not into the future; it will perform poorly when the task requires any of the following:
- searching several moves ahead
  - Chess, Rubik's cube
- complex tasks requiring many individual step
  - cooking a meal, assembling a watch
- logical reasoning to achieve goals
  - travel to New York

Sometimes we may need to plan several steps into the future

# Planning Agent

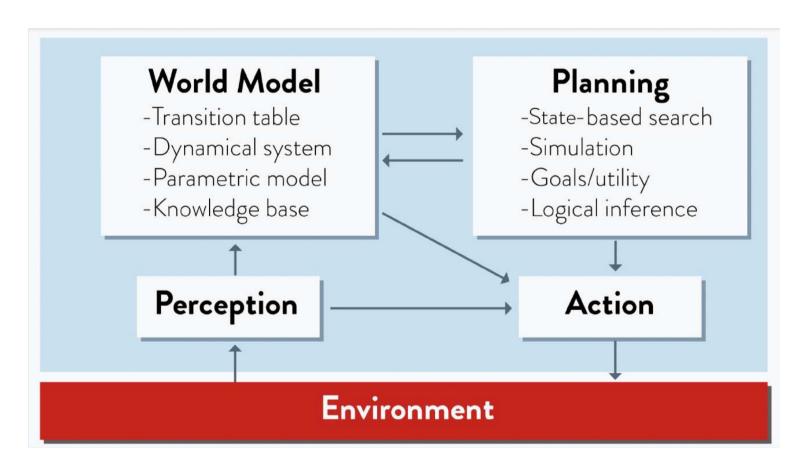

**Goal-Based Agent** 

# Planning Agent

- Decision making of this kind is fundamentally different from the condition–action rules
- It involves consideration of the future
  - "What will happen if I do such-and-such?" and
  - "Will that make me happy?"

In the reflex agent designs, this information is not explicitly represented, because the built-in rules map directly from states to actions

# Models and Planning

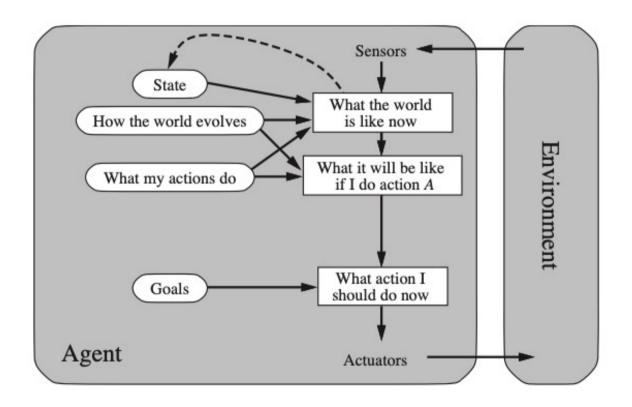

### Reasoning about Future States

- What is the best action in this situation?
- Faking it
  - Sometimes an agent may appear to be planning ahead but is actually just applying reactive rules.
  - These rules can be hand-coded, or learned from experience.
  - Agent may not be flexible enough to adapt to new situations.

### Planning Agent – Goal-based

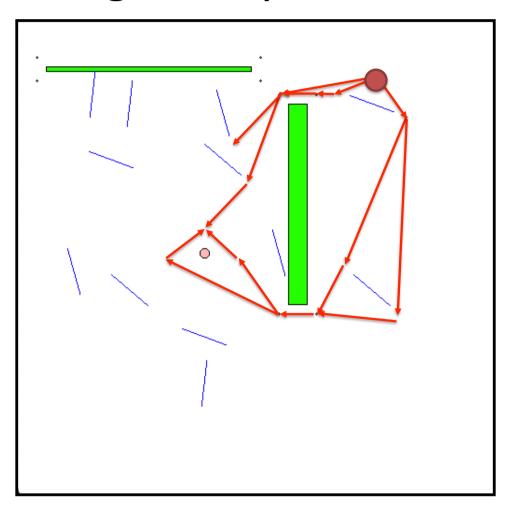

- The planning agent or goal-based agent is more flexible because the knowledge that supports its decisions is represented explicitly and can be modified.
- The agent's behaviour can easily be changed.
- But ....
  - it's slower to react because it has to "think" about what it's doing.

# Goal-based (teleological) agent

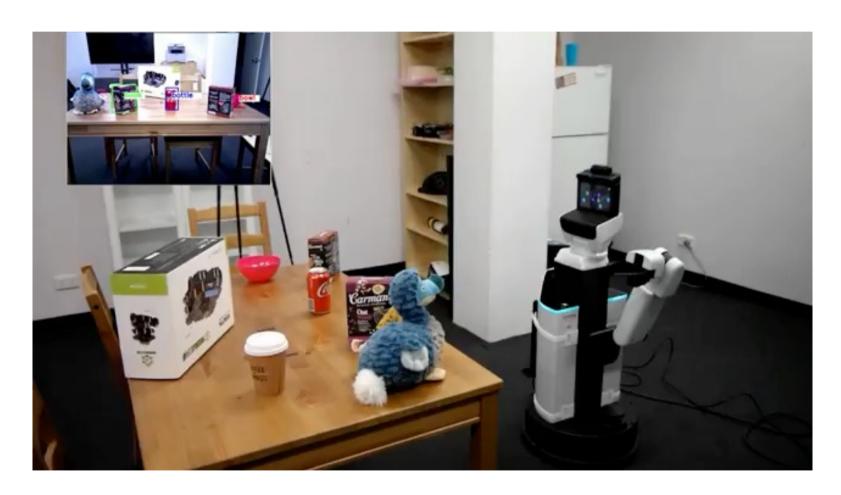

- State description often not sufficient for agent to decide what to do
- Needs to consider its goals (may involve searching and planning)

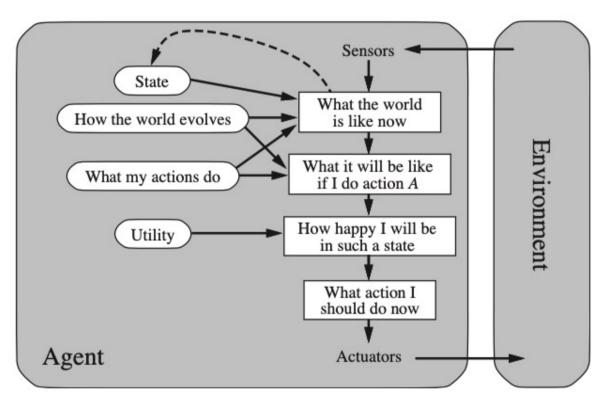

# Planning usually needs search

# @Home Robot

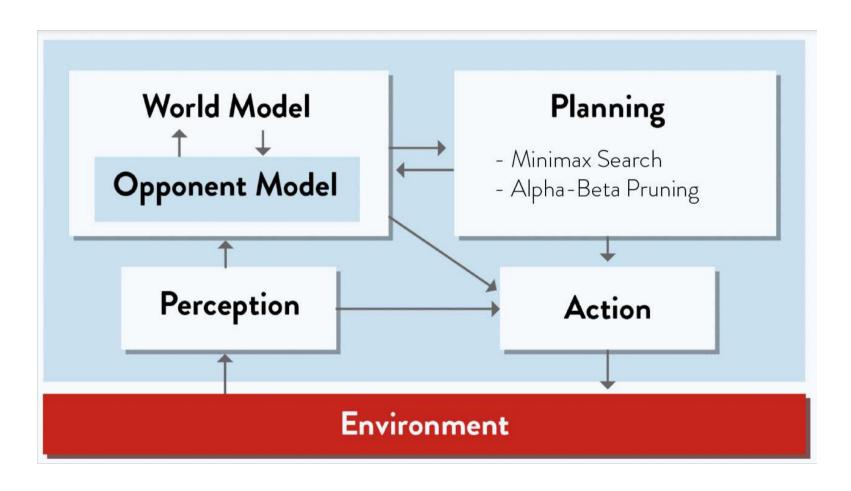

# Utility-based agent

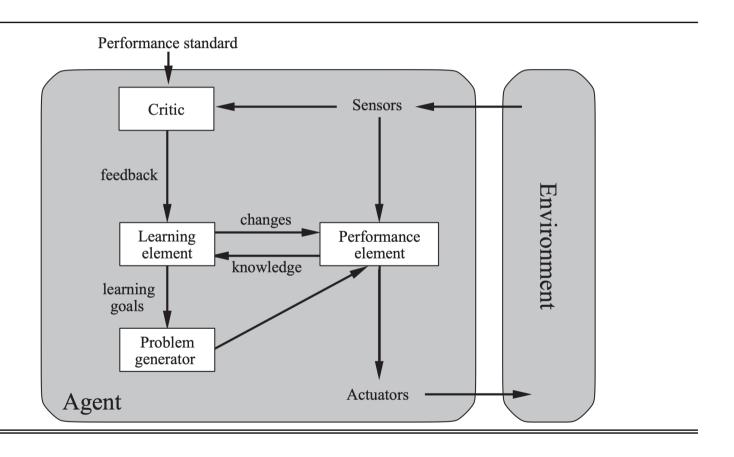

- Model-based, utility-based agent uses
  - model of world
  - utility function that measures preferences among states of world
- Chooses action that leads to best expected utility
  - Expected utility is computed by averaging over all possible outcome states
  - Weighted by probability of outcome.

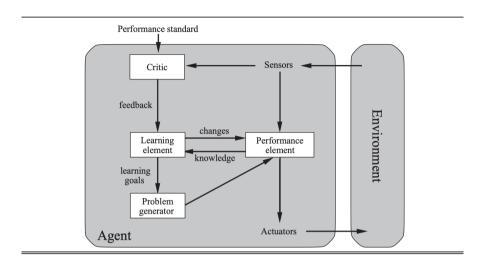

#### Game Playing Agent

# Learning Agent

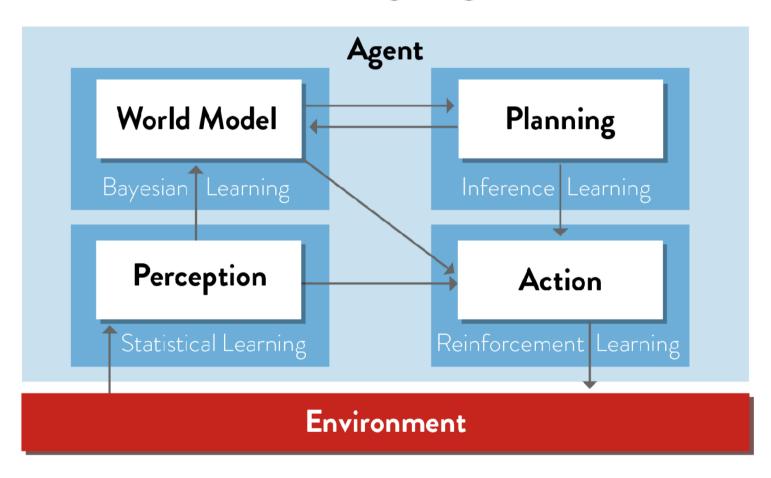

# Learning Agent

- Performance element takes percepts; decides actions
- · Critic gives feedback on how performance element is doing
- Learning element uses feedback to determine how performance element should be modified to do better in future
- Problem generator creates new tasks to provide new and informative experiences.

# Learning Agent

### Learning

- Learning is not a separate module, but rather a set of techniques for improving the existing modules
- Learning is necessary because:
  - may be difficult or even impossible for a human to design all aspects of the system by hand
  - the agent may need to adapt to new situations without being re-programmed by a human

# Summary

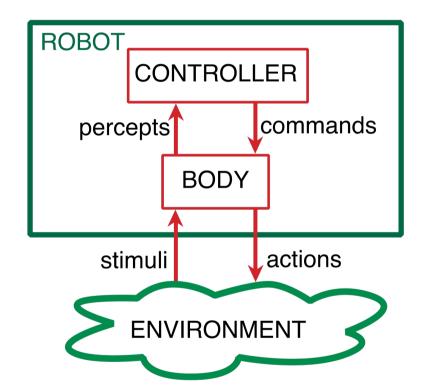

- Reactive agents respond directly to percepts
- Model-based reflex agents maintain internal state to track aspects of the world that are not evident in the current percept
- Planning (Goal-based) agents act to achieve their goals
- Utility-based agents try to maximise expected "happiness."
- All agents can improve their performance through learning.

### Representation and Search

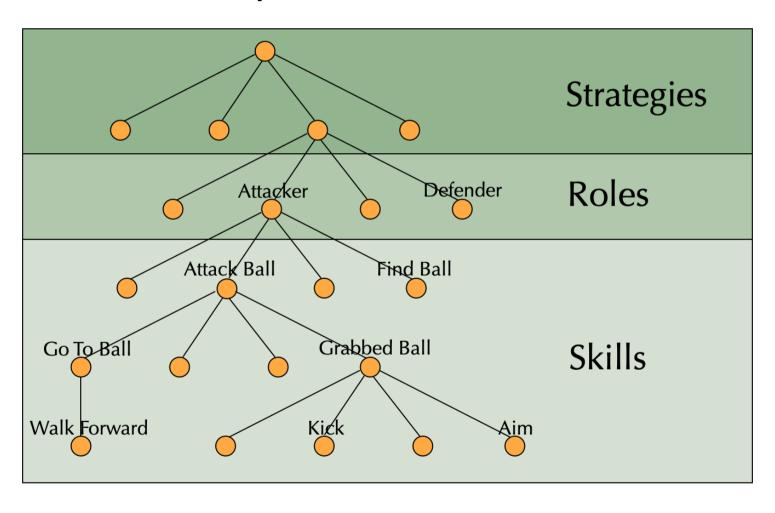

- The world model must be represented in a way that makes reasoning easy.
- Reasoning (problem solving and planning) in Al almost always involves some kind of search amongst possible solutions.

# Layered Architecture

- Hierarchy of controllers
- Controller gets percepts from and sends commands to the lower layer
  - Abstracts low level features into higher level (perception)
- Translates high level commands into actuator instructions (action)
- Controllers have different representations, programs
- Controllers operate at different time scales
- Lower-level controller can override its commands

# Example – Soccer Robot
